

CREATING A PORCELAIN OVERLAY ZIRCONIA BRIDGE

By Luke S. Kahng, CDT, with special thanks to the case clinician, Thomas DeLacey, DDS

Anterior and posterior bridges fabricated with zirconia seem to be gaining popularity with dentists and patients over their porcelain-fused-to-metal counterpart. My concern has been whether zirconia overlaid with porcelain will work for multiple units. Definitely, zirconia offers better translucency and color, especially when there is limited room.

My concern has been the path of insertion. Seating must be all the way down without rocking and with a solid fit. But questions remain: What about longevity? Is it 10 years? And how strong is zirconia overall? These questions can only be answered with time, but most reports thus far have been positive.

ART OF SCANNING

One of the benefits of using the etkon scanning system and outsource milling center is that default or path of insertion problems can be blocked out. In addition, incisal height can be increased or decreased so that the technician's final restoration will have the necessary amount of room to achieve truly esthetic results. The final goal should incorporate how many millimeters tall and wide the prosthesis will be. The frame designed by a computer will not work if the technician doesn't know the full contour. Therefore, it is recommended that the technician have this information before attempting to scan. The

technician will then have more control and proper design over the joint area for support and porcelain longevity.

ART OF THE PORCELAIN

A benefit to the GC ZR lower fusing (810°C) porcelain system is lower dentition. This is better tolerated by the natural teeth because it involves less grinding. From the technician's viewpoint, the porcelain is easy to polish with diamond paste and a wheel.

This case illustration, beginning on page 56, takes you through each step required to create a long-span zirconia bridge. [lab](#)
