Surface Texture
Matching the Single Central

The single maxillary central incisor is perhaps a dental technician’s most demanding restoration. Color, translucency, internal characterization, surface texture and luster are all essential elements critical to its success. While recent innovations in ceramics have greatly improved our ability to match a tooth’s natural color, translucency and characteristic, the accurate reproduction of surface texture and luster remains a mechanical task that requires keen observation, thoughtful planning and execution. Matching the adjacent teeth’s surface texture and luster is as crucial to a restoration’s successful integration as is matching color and characterization and should not be overlooked.

Surface texture directly influences the value, color saturation and zones of light reflection and absorption. An anterior restoration that does not exhibit surface texture and luster comparable to the adjacent natural teeth will immediately appear out of place, particularly when the surface of the surrounding dentition is complex or heavily textured. The natural tooth’s surface is composed of horizontal and vertical concavities and convexities that vary in complexity and intensity from tooth to tooth. Achieving the desired level of esthetics in restorations is rarely possible when these structures are not faithfully replicated.

Complex ceramic layering techniques may showcase the technician’s skill level, but surface texture and luster showcase the restoration.

Case Presentation

A 41-year-old female patient presented with a 20-year-old porcelain-to-metal crown. Beyond the poor esthetics of the crown, the tooth exhibited recurrent decay and the surrounding soft tissue was inflamed. After reviewing the available treatment options, the patient opted for an all-ceramic replacement.

Upon returning to the office, the patient was anesthetized and the existing crown and underlying decay was removed. The tooth was re-prepared and a temporary crown made from Luxatemp Fluorescence (Zenith DMG) acrylic was fabricated.

After surface characterization was applied using the composite color modifiers (Kerr), the provisional was layered with a thin coat of light-cured glaze (Luxaglaze) to fix the color and characterization.

The tooth was then scaled with an ultrasonic scaler prior to cementation of the provisional with a carboxylate cement (Durelon, 3M Espe).

Initial ZR (GC) porcelain color mapping for crown.
In order to achieve optimal gingival health for final impressions, the patient was sent home with a chlorohexidine solution (Oris Rx, Dentsply) and instructed to brush the affected area.

After three months, the tissue health was restored and impressions were taken (Xpasyl by Gunz for retraction, Clinician’s Choice triple tray and Aquasil Decca with LV wash by Dentsply). Before releasing the patient, Polaroid images of the teeth were taken with various shade tabs in view and she was instructed to contact the lab for a custom shade appointment. After a bisque-bake of the crown was complete, the patient returned to the lab for shade verification and further characterization.

During the cementation appointment, the patient was anesthetized and the tooth was lightly air abraded. Simplicity was used to prepare the tooth while an etching gel (Ceretch, Vident), silane and Dentastic Uno adhesive (Pulpdent) were used to prepare the crown. After the excess composite cement was removed (P4 Flowable, Dentsply), the restoration was light cured,

Finished restoration.
utilizing an Ultralume 5 (Ultradent). Any remaining cement remnants were removed using a sharp scaler and a trimming bur (S.S. White #7901). The occlusion was then adjusted and the effected area was repolished with Axis polishing cups and points. A two-week post-operative visit revealed healthy tissue response, no sensitivity and a happy patient.
